

ASSIGNMENT-1

1. Advantages of Java

- Simplicity is the main advantage that comes with Java as a language. Java has a simple syntax that makes it easy to understand and debug. Furthermore, Java is less complex than languages like C++ because many of the complex things like Pointers, operator overloading, have been discarded from Java.
- By reducing the use of pointers, Java decreases security concerns and dangers. In addition, each Java program has a Security manager that allows us to create class access rules.
- As discussed above it is a platform-independent language. Apart from Windows and Mac OS, different platforms where Java is supported are Sun Solaris, RedhatLinux, CentOS, Ubuntu, etc.
- Since it follows the concept of object-oriented programming language, it enhances the flexibility and reusability of the program. In Java, the Java Virtual Machine handles automatic memory management. With the help of the automated Garbage Collection process, Java destroys unused objects automatically.
- Java is considered to be a stable and distributable language as it provides a way for several computers to share data and applications, allowing the system to run faster and more efficiently.
- Because Java programs require a specific hardware infrastructure to execute, they are inexpensive to design and maintain. We can quickly perform them on any system, which saves money on maintenance.
- Java is a multithreaded language, which means that it allows multiple threads to run at the same time. Multithreading allows us to get the most out of our computer's processing power.
- Since Java is WORA (Write once run anywhere) which makes it a platform-independent language it also makes it a portable language. Hence, Java is portable.
